I'm going to be distributing a virtual machine program and would like to let the user set up his own configuration file with paths to the data the program needs just once, so when on later executions of the program it will see the config file is present and get what it needs from it.

Does anyone have suggestions on how the program can discover where it ought to look for the file? The program is going to be distributed to Windows, Solaris, and Linux so I need a solution for each o/s.
