Glenn,

I was just beating on the something earlier this week and this is what I found found out. First off I was looking at voxel type data. I had a bytarr(256,100,100) with some ultrasonic data in it. I was first using volumn() and then passing it on to the render for ray tracing. I thought that this was to easy. Then came time to doing some view changes, transformation of the data, and some nuts-&-bolts type work. I found this was almost impossible using the render. So, I took the same data and this to i

t:

1) vol_pad()

Put zeros around my data

2) center_view,

Create !p.t in such a way my mother would be pleased.

3) vol_trans(data,266,!p.t)

data is the results from vol_pad,266 is my biggest dimensions, and !p.t is my transformation matrix generated by center_view. This function does have a bug in it that only is apparent for large data sets. On line 91 or so $\text{dimsq} = \text{dim} * \text{dim}$. The variable dim is an integer so you get wrap around in the bytes. I changes this line to be $\text{dimsq} = \text{float}(\text{dim}) * \text{float}(\text{dim})$ and and all was well.

4) vol_rend()

There you go. The nuts and blots method.
