Is it possible to plot a set of 2D graphs on the same graph, with the x,y-axes being rescaled to include the entire graph for each overplot?

The problem I am having is if I have two graphs, and the second graph has a larger range than the first graph, both graphs will be on the axes of the first graph instead of the second graph. This clips the first graph which I do not want.

Using the /NOERASE keyword keeps ALL of the axes on a set of plot, instead of the one with the largest range of values.

Ideally, I am looking for a keyword to automatically set the graph axes to the data set with the largest range of values. For example, when using gnuplot, if you "plot func1, func2, func3", gnuplot will draw all three graphs and put them on the scale of the one with the largest values, so that all of the functions can be seen.
