So this will work fine if you have only one IDL session open. But, if
the user starts two separate IDL windows then the xregister won't know
about the other applications. A clunky way to deal with this, is to
use a "lock file", where you write some file to some directory (say /
tmp/ or something) then everytime you start the application you test
if the file exists. If so, then it's running somewhere. Everytime
you close the program, just remember to delete the file...
