Subject: structure arrays with different structures

Hi all,

I'm having some data that's gathered together in different structures and arrays, and I want to collect everything in a structure array in this manner:

```
struct_template = { name:"", select:{}, obs:dblarr(2,100)}
```

I want to put my data into struct\_template, with name being a string, select being another structure, and obs being an array.

I then want to make an array of structures using struct\_template, but naturally with different sets of data.

The issue is that the select structure does not always have the same skeleton, nor does the obs array always have the same size.

The question basically is if there's any way of making an array of structures with the structures sharing the same keys, but with the values having different 'skeletons'

I hope I'm making sense

Cheers,  
Søren
