incomplete stage and can be resumed somehow. The help page for LSODE says that if you set the input status to 2 then that means "This is not the first call. The calculation is to continue normally." I am setting the input status to 2 after it comes back as -1. If you set the status to 1 then it means "initializations will occur."

I don't think it means what you think it means. My understanding is that STATUS=-1 means the routine things it completed with a reliable answer, but it was expensive. You can proceed to the next interval if you wish. If your judgement tells you the result is unreliable, then you probably have to restart the integration or use a different algorithm.

> I downloaded DDEABM a few days ago, but I would like to try to get LSODE to work if possible.
 The reason for status=-1 might have to do with "stiffness" in the system of differential equations. DDEABM documentation says it isn't intended for stiff equations, but my work-around for that will just be to keep subdividing the interval automatically until there aren't any stiffness errors.

Fair enough. Incidentally, DDEABM performs automatic subdivision. According to the original documentation, it can handle mildly stiff equations.
