I'll make another attempt, and this time not just before bedtime...

As I understood your problem, you wanted to remove duplicate rows and then instead co-add them. That would be equivalent to multiply the first copy of the duplicated row with the number of copies. So my idea was to define an array of factors to multiply each row with. It would start out as unity for each row but everytime you found a duplicate you would add one to the position corresponding to the first copy, the one you are going to keep. And when you have found all the duplicate rows, you'd apply those multiplicative factors to the rows before removing the duplicates.
