Subject: Multiple linear regression (MLR): significance of the calculated terms (2 sigma interval)

Hello,

I have been reading MLR results for a while now in published papers. They always talk about the significance of the calculated terms of the regression by saying "it's significant at a 2 sigma level". Is there any body here that would explain to me what it really means and how it is done ? Is it simply when 2sigma is largely superior to the calculated term ?

Thank you for your help
