Do you want a way to use multiple nodes of this cluster or speed up
processing on a single node? Do the nodes have GPUs?

The thread pool is built into IDL and automatically gives some
multi-threading help on certain operations. There is not much you can do
here except tweak some parameters. See the online help for the CPU routine

<http://www.exelisvis.com/docs/CPU.html>

and the Thread Pool:

http://www.exelisvis.com/docs/The__Thread_Pool.html

We at Tech-X have some third-party solutions to these types of problems:

1. TaskDL is a queue-based task farming solution. You create workers
corresponding to cores on a local or networked machine and then add
tasks to a queue. Workers take new tasks as they finish old ones. This
is for "embarrassingly parallel" problems.

2. mpiDL is a set of wrappers for MPI (Message Passing Interface).
This is more complicated and is for problems which require more
communication between workers.

3. GPULib is an easy way to speed up supported operations using
CUDA-enabled NVIDIA graphics cards.

Contact me for more information about any of these products!

Mike
