I have tried using the read_csv command:

data = read_csv(path+'filename.csv',HEADER=SedHeader)

and it it seems to work:
Help, data:
** Structure <2161e08>, 28 tags, length=5600, data length=5600, refs=1:
   FIELD01   STRING   Array[20]
   FIELD02   STRING   Array[20]
   FIELD03   DOUBLE   Array[20]
   FIELD04   DOUBLE   Array[20]
   FIELD05   DOUBLE   Array[20]
.... (I have shortend it here)

print, SedHeader
id full_name diameter H extent ...

Now I would like to have the different columns in the csv out in individuel arrays. But here is my problem, what is the command?

I have tried without luck:
print, diameter
   >%PRINT: Variable is undefined: DIAMETER.
print, field03
   >% PRINT: Variable is undefined: FIELD03.
col3=data(3, *)
print, col3
  >% Attempt to subscript DATA with <INT   (3)> is out of range.

What is the magic word?

PS: I am using a Mac computer
