Alright, here is what is happening. This is a combination of the usual keyword inheritance nonsense, with a little twist from IDL letting you abbreviate keyword names.

The proper way to set axis properties in cgImage is via the AXKeywords keyword, which no one can figure out how to use. So I allow a \*limited\* number of axis keywords to be used on the cgImage command line (e.g., xrange and yrange). I don't forbid you to use XSCALE and YSCALE keywords (the ol' keyword inheritance problem), but there should be no reason to use them, either. cgImage knows what it is doing and does axis things correctly.

Had you actually used XSCALE and YSCALE keywords, instead of their shorted form XS and YS, you would have received an error message, since these keywords are passed along to the TV command. They don't mean anything to the TV command, so the TV command complains. But, in their shortened form, XS and YS, they are interpreted by the TV command as the XSIZE and YSIZE keywords, and they will overwrite the XSIZE and YSIZE values cgImage uses internally to size a PostScript image. (The XSIZE and YSIZE keywords are only used by the TV command when in the PostScript device.) As a result, and this is why you weren't getting an error, your image was being sized to a one-by-one pixel, which was being displayed correctly in your output. :-)

Cheers,

David
