One inconvenience of IDL hashes is that nested hash keys do not auto-instantiate. You must test for the presence of a key, and then create a sub-hash if not found. Other languages let you just say the equivalent of:

```
a=hash()  
a['b','c','d']=1
```

and have all the nested hashes (here: `a['b']` & `a['b','c']`) created automatically. While working around this (i.e. defining nested hashes myself and referencing them), I found a segfault but in IDL 8.4:

```
IDL> a=hash() & c=(a['b']=hash())
```
