As I kill as posts from google, I do not have the original message.

But, in spite of this I have a question!

If the fit parameters are related in some fashion, why not eliminate the 'dependent' ones all together and reduce the number of parameters to be fit? For example if it is known that

$$p[7] = \alpha p[3]$$

why leave  $p[7]$  as a constrained parameter, when it can be removed all together from the problem.

Reducing the degrees of freedom decreased the amount of time needed to find the optimum and can improve accuracy as well.

Scaling the variables to make all parameters lie roughly in the same numerical range is another thing to do ..... but it is a rather different kettle of fish than what I am suggesting.

Do I have the correct picture of what is going on?
