I use a program which generates three matrices for each time step. To plot the data, I combine them into a single image by using the COLOR\_QUAN function

```
image=color_quan([[[mat1]],[[mat2]],[[mat3]]],3,red,green,blue,cube=6)
tvlct,red,green,blue
tv,image
```

and all it is OK. The problem arises when I want to change the colors associated with the image. Imagine that I want to change the colors (red,green,blue) to (white,gray,black) in order to get a suitable image to print in a non color postscript printer. What have I to do? I have tried by loading the color palette black-white (loadct,0) but I don't get enough contrast. In other words, is possible to change the colors RGB coming from COLOR\_QUAN to another set of colors?

Thanks in advance.

RAFA.
