Hi,

How did I get the NO_BLOCK state without using xmanager.

I have written a small interface where I don't want the control of the functions by xmanager. Because xmanager blocks a new event as long as it is running the one before. I have written my own event manager for this application so I am able to create events during an event is processed.

This all is working really good and fast!

The only thing I momentarily don't know is:
How did the NO_BLOCK by xmanager work?.

What is the command for widget_control to get this mode?
