Hi Folks,

I am having problem reading strings from spawned child process (a C-routine). I can read variables (using ReadU :: thanks to comment from David Fanning on pipes being binary). BUT if i read a string using readu, the reading variables from child process go haywire... WHY??? HOW does the readU function treat the string variable?? any suggestions???

thanks

ramji digumarthi

Amen to that. Read bytes, and then convert to a string at the end.

But your specific problem reminds me of a story: A man goes to the doctor and says, "Doctor, it hurts when I do this." The wise doctor said, "Then don't do that."

Seriously, if by \*not\* reading the string variable, everything works fine, are you sure that the string is there?

Craig

I don't know. But I'm really not the person you should be talking  
to. And I wouldn't be trying to write strings anyway. I would  
be writing and reading byte values and casting them back  
to strings. Can't much go wrong that way. :-)

Cheers,

David

WEI!!! I tried that. Either temporary variable (actually recasting the variable as long) or legitimate variable work as long as I do not read the string variable. Once I read the string variable, the next readU of a variable goes hay wire...  
So what gives????

thanks

Well, you can't read into a temporary variable like this.  
Have you tried reading this value into a legitimate  
IDL variable? Does it still not work? I don't see anything  
obviously wrong, except for this.

```
testVal = Long(strInLen)
ReadU, test, testVal
```

Cheers,

David

thanks to the reply from David Fanning about the reading the length of the string array.

I forgot to mention that I do get the length of the string from the C-code, and I do read the string fine.

the problem is on the next readu of variable...

I get grabage.. IF the readU of the stirng commented out than the variable readU works fine .

I am tryin to under stand what happens to readU with reading of the string??? I am also enclosing the both IDL and C-code...

the C-code :::

```
setbuf(stdout,(char *)0);
strcpy(outStr,"Now opening the socket and waiting.\n");
strOutlen=strlen(PoutStr);
fprintf(stderr,"%i :: %d :: %s \r\n",sizeof(strOutlen),strOutlen,outStr);
write(1,&strOutlen,sizeof(int));
write(1,outStr,sizeof(outStr));

read(0,&Next_data,sizeof(int));
fprintf(stderr," value read from parent : %d\r\r\n",Next_data);

strOutlen++;
write(1,&strOutlen,sizeof(int));
```

the IDL code :::

```
readu,test,strInlen
;string_in=string(replicate(32b,strInlen+1))
string_in=string(bytarr(strInlen))
```

```
readu,test,string_in,TRANSFER_COUNT=countVar
print,"Str len ::",strlen," == ",string_in,countVar,size(string_in)

writeu,test,strlen

readu,test,long(strlen)
print," Test .. :",strlen
```

-----

any comments on why this code does not work!!!!

thanks  
ramji digumarthi

Prepare to shoot me down if I'm wrong, but it looks to me as though you are writing the wrong number of characters from the string here. You don't tell us how you have declared outStr, but in C I

would think it is either a char pointer or a char array. The former will have `sizeof() = 4` (or 8 if a 64 bit system) and the latter will be the length of the array regardless of what is in it.

Shouldn't you write `strlen`, or `strOutlen` bytes, which is the integer you are writing before it as its length?
