A few quick thoughts for you. If I understand your problem correctly, I had a similar problem recently.

I had a problem a few months ago (spring 2000) when I found that in **some** cases (IIRC mostly to do with DG plots with two y-axes), there was IDL output outside of the IDL-drawn BB.

Do a search for my name and you'll find the thread with some good suggestions from others that ultimately solved my problem.

IIRC I came up with two other workarounds.

- 1) Change the BB by hand in a text editor.
- 2) Have LaTeX clip the graph outside the default BB. This may require a BB specification with negative values, e.g. `bb= -10 -10 250 250` or whatever the proper syntax is for `\includegraphics` or whatever graphics-inclusion-command you are using (I forget right now the exact syntax of this command).

HTH,
Andrew
