I would like to display RGB images, with, for instance higher values for the Red component causing redder colors, and higher values of the blue component making them bluer. I used to be able to do that pretty easily, using the

```
tv,image,/true
```

However, since I've been moved to a Linux workstation, it doesn't work. I could provide detailed symptoms if you want, but it's obviously a configuration problem, so maybe the easiest way is to ask how I need to configure my IDL session to display these things properly. Attached is a copy of the xdpinfo output for my system. What device commands should I use?

Another good idea would be weekly score cards to rate how satisfied you are with your sysadmin. This could also be filled out after help has been given.

:)

As long as they're allowed the same forum to express their opinions of your questions. It would give you management an idea of how much more training you might need.

I prefer the egalitarian rather than the elitist approach.

Along with a score card for the sys admin to rate the cluelessness of the users, and perhaps a prize for the daftest request of the week?
