I require assistance with an odd problem. My current projects involves creating a dlm module of some 200+ routines from a library of 1500+ routines. Several of the IDL callable routines replicate intrinsic IDL calls. While testing one such routine that calculates determinate of a 3X3 I encountered a problem. The numerical result between my determinant function and determ matches to $10^{(-16)}$.

Now the odd thing. Under certain circumstances the use of my determinant function as an argument in another routine call causes an error:

% Program caused arithmetic error: Floating illegal operand.

Code causing error:

```
cspice_eul2m, 30.d0, 60.d0, -15.d0, 3, 2, 1, mat1
```

```
cspice_chksd, "Determinant of rotation matrix", cspice_det(mat1), $  
    "~", 1.d0, LIMIT, ok
```

The first routine, cspice_eul2m, calculates a rotation matrix given the rotation angles and the sequence of axes. The second routine, cspice_chksd, performs a tolerance test on the determinant of mat1, calculated by the function cspice_det(mat1).

If I replace cspice_det(mat1) with determ(mat1), no error. If I recast the code as:

```
cspice_eul2m, 30.d0, 60.d0, -15.d0, 3, 2, 1, mat1  
det = cspice_det(mat1)
```

```
cspice_chksd, "Determinant of rotation matrix", det , $  
    "~", 1.d0, LIMIT, ok
```

no error results.

Also, a different sequence of rotations exhibits no error. I have several similar tests involving other matrices without error.

Any suggestions?

As always,
