
Subject: best way to find the variable name of a structure from RESTORE-ing a sav file

anyone have good ideas on how to programatically find the name of a variable in memory, that happens to be a structure. The reason I don't know the name is that I am restoring a structure from an IDL sav file. The structure is the only thing in the sav file.

For instance, I am writing a function like:

```
function readsavdata, filename
```

```
restore,filename=filename
```

```
; here I have a structure in memory, with a variable name I do not know.
```

```
help
```

```
; next line is the result of the help command
```

```
; IDL> NWS_MMT_FCAST_TEMPERATURE_ARRAY          STRUCT  = -> <Anonymous>  
Array[950040]
```

```
return, ?????? ; i need the name of this structure
```

```
end ; end of function
```

How do I get this variable name "NWS_MMT_FCAST_TEMPERATURE_ARRAY" so I can put in a line like

```
return,NWS_MMT_FCAST_TEMPERATURE_ARRAY
```

at the end of the function. I suppose I can capture and parse the help command and issue an execute command, but there must be a way to find that info that is a little nicer.

Cheers,

bob
