I can't say why REBIN doesn't take complex args, but I can say that you have to be very careful when you interpolate complex values if you want to have meaningful results.

Consider these two numbers

$z1 = \text{complex}(1,0) = 1.$

$z2 = \text{complex}(-1,0) = -1.$

Suppose you were using rebin to reduce the size of a linear array by 2.

Which of the following behaviors would you want?

You could separately average x and y like this, and get zero:

$z\_avg = (\text{complex}(1,0) + \text{complex}(-1,0))/2. = \text{complex}(0,0) = 0$

Or, you could respect the fact that the phase changes by 180 degrees but the amplitude doesn't change at all. So,

$z\_avg = \text{complex}(0,1) = i$

This second value would come from

$z1 = r1 * \exp(i * \theta_1)$

$z2 = r2 * \exp(i * \theta_2)$  ;--- note  $i = \text{complex}(0,1)$

$z\_avg = ((r1+r2)/2.) * \exp(i * (\theta_1+\theta_2)/2.)$

To accomplish the first mode, you could break up and separately REBIN  $\text{real}(a)$  and  $\text{imaginary}(a)$ .

To accomplish the second mode, you could break up and separately REBIN  $\text{abs}(a)$  and  $\text{atan}(a, / \text{phase})$

Ahh, of course. I knew it would be something like that - I had a similar problem with MEDIAN a few months ago. I'm only using REBIN to expand a 2D array to 3D (containing the same values) so I just

separated Re and Im and REBINned them separately, easy.

Thanks.

This one. It's what all the other flavors of REBIN do.

It's the "compress" form of REBIN that I would be really interested  
in, i.e. the ability to sum up loads of complex values.
