Hey all again,

Thanks for the help with the objects.
I have a feeling I know what the answer to this question is going to be...:)

The problem in my previous problem was due to the fact that the my event handler was seperate from the class. This class creates so I thought the obvious solution would be to make a compound widget, i thought I was being really clever.

However, the problem I ran into was, my class contains the "TLB", and various Draw Widgets and buttons.

So, the line:

Widget_Control, self.idTLB, EVENT_PRO= Class_Event_Handler does not allow me access to the class at runtime in the Event_Handler...i didn't feel so clever anymore.

I tried to put the tlb within another base, with simliar results. Is there anyway around this?? Or does EVENT_PRO and EVENT_FUNC just meant to be used with Draw Widgets, and Buttons. I think I see why someone decided to go and build their own widget wrapper library.

Thanks again,

Sabir Pasha
