Dear all

While the good "dongle" isn't available with idl6.0 we thought to use a pcmcia network card for traveling one IDL license to different notebooks. The card is moved to the notebook which should get the license. We got different results for windows and linux.

on windows:

Imhostid compares every available network mac address with the license information. The notebook with the additional network card is able to use the idl license defined to this pcmcia card

on linux:

Imhostid queries always only the first ethernet card (eth0). The others are ignored.

I hope someone has an excellent idea how to get the Imhostid querying an other network card too. Or is this a bug?

best regards

Reimar

I cannot answer your specific question, but I was wondering if you have considered using the new Personal Use license which allows you to install and use IDL on multiple machines?

Dear Robert

The personal license is only useful if you have yourself more as one machine and noone of your colleagues are using this machines too. It's only a personal license for the owner not for a different user on the same machine.

The personal license is only for windows or only for linux. This can't be mixed.

Actually not true, the personal liscence can be mixed between two OSs.
How do I know?? well my colleague harassed RSI and then he got a
personal license to work both in windows and linux. Practically
speaking he doesn't switch too much between the two, but it's still
nice to have.

good news I hope CREASO could do the same. But it does not solve the
problem.
