If I have a pop-up window that was started from within an event handler for the primary widget, and I am using the primary widgets event function code to handle the events (see below), how do I maintain the link to my state data when the pop-up access the event function code?

```
widget_control,'air',tlb,/realize  
xmanager,'air',tlb,event_handler='the same piece of code it is already  
in',/no_block
```

When the code enters the event handler the first time, in response to a button click in the primary widget, the state information is dutifully kept, but when it enters the event handler from the pop-up window (same event handler mind you as the last call) I have lost all of the links to my state data, primary_widget id, etc.

I have tried setting the uvalue of one of the pop-up windows to the state information, generally keeps this, but loses the widget id of the primary tlb.

So can 2 top-levels bases see each other and exchange information? I know they can I just cant seem to figure it out properly. Its driving me nuts.

Cheers in advance. Andrew
