Hello group

I found out that when reading unformatted data, written with a fortran 90 program, the readu command detects a couple of extra records before and after each line written with the fortran program. For example, I wrote a 10x10 array, containing the numbers from 1-100 in a file. Reading the file using readu, the content of the file appears as a 14x10 array, with very small numbers in columns 1, 2, 13 and 14, (producing floating underflow), and the correct numbers in the columns 3-12.

In the data file I actually had to read there are three extra records before and two after each line.

These extra records do certainly not appear when reading the files with a fortran program.

I was curious if anyone had an explanation of this.

Regards, Hjalti

You'd probably be surprised by what can be done with them. :-)

Cheers,

David
