What is the problem your are having? Is it that findfile does not work at all or that findfile does not find your image files? This is an important difference and not quite clear from your message. If the latter is the case, have you tried specifying the full path in the search command?

Haje

BTW: findfile is pretty much obsolete. The replacement, file\_search, is much better.

Thanks a lot for your response, Haje. findfile just doesn't find anything, and I have tried specifying the full path. It doesn't work! Thanks for your suggestion on file\_search. The problem is I'm using a lot of routines that were written by other people and frequently use findfile in them, so I would have to modify a lot of files if I were to change all of them to file\_search.

Do you have any ideas as to how to fix this?

Many thanks again,

Ali

What do you get when you type

```
result = findfile('c:\path\to\images\*.jpg')
```

You may want to replace \*.jpg with the true extension of your images?

When I type this command and hit return, it doesn't give me any messages at all. I then typed the following:

```
result = findfile('c:\path\to\images\*.*', count=nf)
```

and then

```
print, nf
```

it prints 0.

A couple of suggestions:

your filename is almost certainly to blame.

0) use file\_search. Seriously.

1) To be certain you have the correct path, try to read the tif file

filename = '/group2/Ali2/071805/6535j2/6535j20001.tif'

```
f=findfile(filename,count=nf)
```

```
help,f
```

```
Result = READ_TIFF( Filename)
```

```
help, result
```

```
f_search=file_search(filename)
```

```
help,f_search
```

2) are the files ending in tiff rather than tif?

3) is it a network drive and the access is too slow (so the command times out?)

4) so if you can get the much better file\_search() routine to work, perhaps you could

overwrite the findfile routine (i don't remember ver 5.6, is findfile a \*.pro routine?)

Anyways, if you could write a findfile routine that just called file\_search, that may solve

the problem. Disclaimer, this would be a pretty bad hack, completely non-portable,

and certain to cause great error and confusion in the future. Only soulless demons

like myself would even consider the idea. You'd be much better off changing every

call to findfile in all your source code.

5) do you have a HUGE number of files? That could be a problem. I ran into a

real damaging bug reading satellite data files, because my findfile routines would

return something like 98% of the files that actually existed, causing my robust code

to handle the "missing data" when it was in fact not missing.

In one case, I had to actually cd to the path, and get the current listing

```
cd,cur=cur
```

```
cd,subdirectory
```

```
files = findfile('*.'+filetype,count=num)
```

```
cd,cur
```

That was an operating system problem, that went away with the next upgrade (sorry I don't remember what version, it was a redhat linux of a couple years ago).

Cheers,  
bob
