Hello!

Following the trend of questions on histogram, I was wondering if there is a way I could clip a particular peak of a histogram, meaning I could obtain the data only for that particular peak and store it somewhere, of course without my intervention. All I know is that I want the histogram above a certain threshold. The function should clip the peak appearing subsequent to the threshold upto the point where the curve touches the base.

for termination, we could say something like if (hist[x] < 50) stop = 1.

how abt the beginning.? How do I know that a peak is about to begin?

Any thoughts?

Thanks,
Pravesh
