Using DC_TIFF_WRITE, I can output image file from PV-Wave which I can then re-load at a later data. This is not a problem for any of the four classes (Bi,gray,palette and RGB). When I try to read the colour plots into another package it the image is a mess. So far I have tried Imagetool (Solaris 2.3) and xv on UNIX, and I have even transferred the file to a Mac and tried Photoshop, all to no avail.

This would seem to imply that the problem is with PV-Wave and they way it outputs an 8 or 24-bit image. I know how to create the pallette array as well as obtaining an MxNx3 image array for the 24-bit RGB output, but none of this can be read by anything else I've tried (Bi and gray do work however).

I'm about to pack it in and tear up the manuals page by page!
Am I just daft or is there something I'm missing?

- help!
