I've sucked it up, I think I need a push in the right direction. Imagine that I have a long (~6 million points) list of data that includes three fields: latitude, longitude, abundance. The lats and lons are all over the place (i.e. no regular grid) and I'd like to bin them into an image. Additionally I'd like to average abundance of each bin to be the color for the image.

I can use the reverse indices keyword in histogram. I can even use mean pretty well. I can get a binned histogram using `histo_2D`. But I'm having a hard time thinking about how to go from the reverse indices of histogram to the `histo_2D` case which doesn't offer the same keyword. The only way I can think of to do this is to:

- a) do a histogram of the latitudes (using RI)
- b) do a histogram of the longitudes (using RI)
- c) find the intersection of indices for each bin that I want
- d) "flatten" the lat, lon, indices/abund cube with matrix multiplication

It's the "c" part I'm sketched out on, my brain's can't think around anything but a very evil Loop.

Has this really easy or been answered here before? (Array decimation was the closest thing I found).

Thanks in advance!
