
Subject: rotation matching of 2D images

Hello!

I have 2 images of same sizes, but different orientations.
One of these images is my 'reference' image, and the other one is the
'target' image, that I would like to rotate, so that the orientation of
its features match the orientation of the reference image.

I would then need an algorithm performing some kind of
cross-correlation and returning the adequate rotation angle(I could
then use the idl function ROT afterwards).

Does somebody have a clue of such a procedure ?

Many thanks
