Subject: A smarter way to do this...

Hi all,

   I'm looking for a smarter way to solve the following problem... any
help is appreciated..

I have an array of structures with a specified size as follows : info =
replicate({name, label:'', vector:floarr(1000)}, size)

Each structure has 2 fields, the parameter and a vector: info[i] =
{name, 'ParameterName', ParameterVector}. (Note: i cannot change this
format)

for example, info[0] = {name, 'paramA', vectorA}
            info[1] = {name, 'paramB', vectorB}
                                    ...

My goal is make a vector with its own parameter name:
paramA = vectorA
paramB = vectorB

but it can be tedious when the "size" is large...don't really want to
list them for 100 times.  Is there a smarter/easier way to loop this?
or I'll have to list it by hand how ever many "size" times?
