Subject: Create Project Question

Folks,

OK, this is a question I asked before, but didn't get a satisfactory answer for. I am working in a new IDL Workspace. I am trying to create a project in this workspace from a directory that I made this morning and that is completely divorced from where I normally store my IDL files. I made this directory and I copied into it other directories containing files that I want to have under Subversion control.

So, I have added these files to my Subversion repository. Then I completely emptied the directories. Now I am trying to check files out of the repository and into them. But I cannot create projects from these existing directories. I am told that the location C:/david/coyote (the new location) "overlaps the location of another project: Coyote".

What is this about? I have looked in the david/coyote directory. It is completely empty. I have NOT copied .project files into the repository. (I removed them before I imported them.)

Any ideas? I've made LOTS of projects named Coyote. It's a motif. But, please, let me start over the right way. I really don't want a project named "Rabbit". :-(

Thanks,

David
