If you mean that you specify colors as 24-bit values, then
you simply need to set DEVICE, DECOMPOSED=1 before you
use your colors. ATV is almost certainly written so that
it sets DEVICE, DECOMPOSED=0 for its colors.

If you mean you specify colors as 8-bit values (like ATV
does), then you have no choice but to load your colors
before you use the colors. There is only one color table,
and ATV changed it.

The only other alternative (which I am having a hard time
getting across to people) is to use color tools that
work around this problem. FSC_COLOR is one such tool.
If you used that to specify your colors there is a very
good chance you wouldn't be writing this morning. :-)

Cheers,

David

Hey Thanks so much. I do specify my colors as 24-bit values. And you
were right. That was the problem. It worked after I set the device. I
remember doing this earlier. I feel stupid. Thanks so much again.
