So, I just got the operating system on my 4-year-old 64-bit machine upgraded to 64-bit Fedora, and am basking in the joys of 64-bit IDL. However, I have found:

- 1) It is still possible to get the dreaded "cannot allocate memory" error;
- 2) MEMTEST.PRO, my trusted advisor for years, produces nonsense results in 64-bit IDL.

What are the limitations I am operating under here? How do I evaluate the memory state of 64-bit IDL?
