Hi all,

I'm using David Fanning's progressbar procedure to show the advancement of a time-consuming routine, but I have a problem. The progressbar works ok, but since each cycle of the operation that I'm conducting take a couple of minutes to complete I have some problems in the "updating" of the window. The window infact updates itself only at the end of each cycle, and if I open a window "over" the progress bar and then close it then the progress bar window appears "blank" until the start of the next cycle. Moreover, and this is the worst problem, the "cancel" button of the progress bar does not work. I believe this is because IDL is busy at making "other things", and the program isn't able to catch the button press events.

Does anyone know if there is a way to overcome this problem ?

Thanks in advance for the help,

Lorenzo

Hi Andrew,

thanks for your suggestion.

However, as far as I understand in order to distribute an IDL application in the way that you suggest I have to use the "MAKE\_RT" procedure to build a "runtime application". By searching on the web I found out that "Runtime applications are just a way of packing a compiled program (the sav file) and the virtual machine together, so that the person to use your program does not have to download and install the virtual machine". As far as I understand, runtime applications should therefore have the same limitations of SAV files "shared" with the VM (i.e., no execute method on the IDL\_IDLBRIDGE).

Am I correct ? Did anyone try to build a runtime application which involved the use of the IDL\_IDL bridge ?

Lorenzo
