
Subject: IDL/DLM segmentation fault on reset

Hi,
Have an interesting problem for DLM programmers out there. I have a C code for Linux that sets an environment variable using putenv() within a DLM. The code executes as designed but when I issue a .full_session_reset I get a segmentation fault and IDL exits ungracefully. I run the same code (with slightly different calling convention) under Windows without problems. Does anyone know why? Do I need some sort of exit handler for the DLM (similar to IDL_Load for startup)?

Haje
