Hello,

I have been trying to pick up good programming practices by copying what other people do. What I have not been able to figure out, though, is error handling.

Right now, I tend to check all of the input parameters and keywords to make sure they are suitable for the program that follows. But then again, there is the whole RTFM argument. When do you check a specific input parameter and when do you just throw/catch an error and return to main?

Thanks
