
Subject: widget crashes and restarts

Okay, I give up,

If you have a widget application that crashes somewhere in the event handler, how do you (a) remove the current widget and (b) make sure everything is okay when you start the widget application again?

I can destroy the widget either by closing the Xwindow or by typing WIDGET_CONTROL, /RESET. But then when I start up the widget again it is unresponsive; the buttons and menus can be manipulated but they don't call the event handler. Right now the only way I know of to restart the widget is to exit and restart IDL.

Thanks,
Mark
