Subject: Very basic IDL vector question Posted by kubota on Tue, 03 May 2016 06:24:41 GMT

View Forum Message <> Reply to Message

I am trying to understand the operation of an IDL program. There are several lines using vectors which I do not understand.

The first line is:

fc = call\_function(fun,xc)

Here, xc is a vector.

Is fc a scalar or vector, being that xc is a vector?

If fc is a scalar, which element of xc is being used for the function calculation?

If fc is a vector, does that mean that the vector fc is filled with all the function evaluations of the x values in xc?

Thanks for any assistance.
