I have a 2-d plot (which is a projection of some 3-D data) displayed with a colorbar scale underneath. When i invoke the canned slicer on the 3-D dataset, with the 2-D plot window remaining on the screen, the colorbar in all the other windows gets taken over by the slicer, which appears to be repeating the same color table 3 times within the space allocated space. I can avoid this problem by doing my slicing first and then doing the 2-D projections, or i can close down all the 2-D plot windows before invoking the slicer, but both of these 'solutions' are kludges. Does anyone have an idea as to what's going on and how to fix it? I noticed somewhere in the slicer code it says something about calling the color table 3 times, one for each face of the cube.
