
Subject: Windows version - problem with suspend/resume?

I recently installed a Windows version of IDL 5.2 on my IBM ThinkPad 560Z, running Win98. It uses a hardware key. I noticed that if I put the computer into suspend mode after running IDL, it fails to boot properly and I end up staring at the blue screen of death. Suspend/resume works fine before running IDL, but if I run IDL once and exit from IDL, then try to do a suspend/resume, it fails. Is this a known bug, and if so, is there a way to get around it?
